Key words: AERD. FeNO. Bronchial challenge. Phenotypes.

Palabras clave: EREA. FeNo. Provocación bronquial. Fenotipos.

Aspirin-exacerbated respiratory disease (AERD) affects patients with asthma, chronic rhinosinusitis (CRS), and nasal polyposis with airway reactions following the ingestion of nonsteroidal anti-inflammatory drugs (NSAIDs) [1]. Bronchial challenge with lysine-acetylsalicylate (L-ASA) is a safer diagnostic method for aspirin-induced asthma (AIA) than oral challenge, although it is less sensitive [2]. Fractional exhaled nitric oxide (FeNO) is a marker of type 2-driven inflammatory mechanisms in the airway [3]. The association between changes in FeNO levels and exposure to NSAIDs in specific bronchial challenge has not been well characterized. The aim of this study was to evaluate changes in FeNO levels after bronchial challenge with L-ASA in patients suspected of having AIA. The local ethics committee approved the study, and all patients gave their written informed consent (PI-2860).

Asthmatic patients aged ≥ 18 years with symptoms of AIA evaluated at the Allergy Department of University Hospital La Paz, Madrid, Spain from 2009 to 2016 were included. FeNO was measured using a portable nitric oxide (NO) analyzer (NioxMinoTM, Aerocrine) immediately before the bronchial challenge (baseline FeNO/FeNOpre) and 24 hours after L-ASA challenge (FeNOpost). The increase in FeNO levels was calculated by subtracting FeNOpre from FeNOpost. Baseline FeNO < 40 ppb was considered normal [3]. Bronchial challenge with L-ASA was performed using an electronic dosimeter (Spire Elektro, Respiratory Care Center) following previously published protocols [2,4], according to which increasing doses of L-ASA were inhaled every 30 minutes up to a maximum accumulated dose of 127.9 mg. A provocative dose causing a 20% fall in baseline fractional exhaled volume in the first second (FEV₁) (PD₂₀) was calculated based on linear interpolation between points on the log dose-response curve. Bronchial challenge was considered to be positive in the case of an early response in the form of a drop in FEV₁ $\geq 20\%$, a prolonged early asthmatic response, and a dual response or late asthmatic response. Bronchial challenge was negative

Table. Characteristics of the Study Population

	AIA (Positive BC L-ASA)	Aspirin-Tolerant Asthmatics (Negative BC L-ASA)
Gender		
Male	9 (37.5)	24 (47)
Female	15 (32.4)	27 (53)
Mean (SD) age	44.42 (16)	41.66 (16)
Mean (SD) body mass index	25 (3.5)	25.14 (5.4)
Smoking habit, No. (%)		
Smoker	6 (25)	9 (18)
Nonsmoker	18 (75)	42 (82)
Personal history of atopy, No. (%)		
No	14 (61)	41 (80)
Yes	9 (39)	10 (20)
Previous diagnosis, No. (%)		
Asthma	3 (12.5)	10 (20)
Asthma, rhinitis	7 (29.1)	26 (51)
Asthma, nasal polyposis	14 (58.3)	15 (29)
Median (IQR) baseline eosinophilia	245 (3440-30)	260 (0-1400)
Median (IQR) total IgE, kU/L		
Severity of asthma, No. (%)		
Moderate	15 (62.5)	28 (55)
Severe	9 (37.5)	23 (45.1)
Baseline lung function		
FEV ₁ , % predicted	97.41 (19.4)	99 (15)ç
FVC, % predicted	109.11 (15)	107 (13.4)
Median (IQR) baseline FeNO, ppb	43 (11-115)	27.50 (9-134)
Clinical reaction NSAIDs, No. (%)		
Cough, dyspnea, wheezing (CDW)	10 (59)	15 (43)
Dyspnea	1 (6)	8 (23)
CDW + rhinitis	3 (17)	5 (14)
CDW + urticaria	2 (12)	3 (9)
Rhinitis + dyspnea	1 (6)	4 (11)
NSAIDs involved, No. (%)		
Aspirin	7 (28)	18 (36)
Ibuprofen	9 (36)	16 (32)
Metamizole	8 (32)	15 (30)
Aspirin + other	1 (4)	1 (2)
Median (IQR) PD ₂₀ BC L-ASA	29 (2.06-65)	
FeNO, ppb		
Baseline	45.5 (33.6-57.5)	37.3 (29.1-45.4)
24 hours postchallenge	54.5 (39.6-69.5)	39 (28.8-40.2)
Incremental FeNO, ppb	9 (2.9-15)	1.7 (-2.4 to 5.8)
P value	.004	.409

Abbreviations: AIA, aspirin-intolerant asthma; BC, bronchial challenge; FeNO, fractional exhaled nitric oxide; FEV₁, forced expiratory volume in the first second; FVC, forced vital capacity; L-ASA, lysine-acetylsalicylate; NSAID, nonsteroidal anti-inflammatory drug; PD₂₀, provocative dose causing a 20% fall in baseline FEV₁.

if the maximum dose was reached and no drop in FEV₁ or peak expiratory flow $\geq 20\%$ was observed in the following 24 hours [2,4]. At the time of bronchial challenge, patients had to have withdrawn their regular treatment as per EAACI guidelines [4]. Data were analyzed using SAS v9.3 (SAS, Institute). The groups were compared using the χ^2 test. Nonnormally distributed variables were compared using the Mann-Whitney test and multiple comparisons using the Bonferroni test. A *P* value $\leq .05$ was considered significant.

Seventy-five patients (56% women) were included. Forty-three (57%) had moderate persistent asthma, and 32 (43%) had severe asthma. The clinical characteristics are listed in the Table. Twenty-four patients had a positive bronchial challenge result (32%): 17 with an early asthmatic response, 1 with a prolonged early response, 4 with a dual response, and 2 with a late isolated response. Fifty-one patients had a negative result (68%). Seventy-two FeNO_{pre} and 66 FeNO_{post} measurements were performed. A significant increase in FeNO levels (9 ppb [3]) after bronchial challenge was found in patients with a positive result with L-ASA (*P*=.004), whereas no significant increase in FeNO_{post} (1.7 ppb [2]) was observed in the negative bronchial challenge group (*P*=.409). Regardless of baseline FeNO (FeNO_{pre} <40 ppb and ≥ 40 ppb), patients with a positive bronchial challenge result experienced a significant increase in FeNO after bronchial challenge with L-ASA (*P*<.001). This was not the case when the result of the challenge test was negative (*P*=.527). The median (IQR) peripheral eosinophil count was 245/mm³ (30-3440) in positive bronchial challenge and 260/mm³ (0-1440) in negative bronchial challenge. This difference was not statistically significant. No significant differences were found for the other variables analyzed (Table).

AIA was confirmed by bronchial challenge with L-ASA in 32% of patients with a suspected clinical history of reaction to NSAIDs. This finding is in line with previous publications by our group [2]. A significant increase in FeNO levels after the L-ASA inhalation test was observed only in AIA confirmed by a positive bronchial challenge (*P*=.004). Increases in FeNO levels after bronchial challenge with specific allergens have been reported [3]. In contrast, Jerschow et al [5] reported a decrease in FeNO levels after oral challenge with 40 mg of aspirin. We speculate that this difference could be due to the type of challenge (oral vs bronchial) and/or the timing of measurement of FeNO levels (24 hours after challenge vs during the first hour after administration of aspirin) [5]. Moreover, the patients in the studies reported did not present a decrease in FEV₁ $\geq 20\%$ after oral aspirin, whereas all of the challenge-positive patients experienced a drop in FEV₁ $\geq 20\%$ [5]. The only study to investigate AIA and changes in NO levels after challenge with L-ASA was performed in 2009 by Rolla et al [6], who determined whether inhalation of L-ASA could affect FeNO levels in patients with previously confirmed AERD. The study included only 20 mild asthmatic patients and 10 nonasthmatic patients as a control group, in contrast with the 75 asthmatic patients (43 with moderate persistent asthma and 32 with severe asthma) included in the present study. Similarly, Rolla et al obtained a significant increase in FeNO_{post} only in the challenge-positive group (*P*<.001). FeNO_{pre} levels were similar in both studies (29.5 ppb). The increase in FeNO_{post}

levels we observed (9 ppb) was lower than that reported by Rolla et al and can be explained by the heterogeneous clinical characteristics of patients included in both studies. For example, 89% of the patients were diagnosed with CRS and/or nasal polyposis compared with the 33.3% prevalence of rhinitis. The authors reported a significant correlation between the increase in sputum eosinophils and the increase in FeNO in AIA patients after inhalation of L-ASA as an indicator of a type 2 inflammatory phenotype [6]. In recent decades, IL-13 has proven to be an inflammatory cytokine involved in the type 2 pathway, particularly as a key regulator in NO production and in recruitment of eosinophils in the airway [7-9]. Based on these findings, the inflammatory mechanism may explain the increase in FeNO level in AIA patients after bronchial challenge with L-ASA. Similarly, it can be hypothesized that cytokines such as IL-5, IL-4, IL-13, and even IgE play a vital role in the pathogenesis of AERD, enabling AIA patients to benefit from therapy with biologics [7-10].

To the best of our knowledge, we report the first large sample of patients with severe and moderate asthma in whom changes in FeNO levels after bronchial challenge with L-ASA have been evaluated.

Acknowledgments

The authors would like to thank Rosario Madero for the statistical analysis.

Funding

The authors declare that no funding was received for the present study.

Conflicts of Interest

The authors declare that they have no conflicts of interest.
